FSCQ-Series:

FSCQ0565RT / FSCQ0765RT / FSCQ0965RT / FSCQ1265RT / FSCQ1565RT Green Mode Fairchild Power Switch (FPS™)

Features

- Optimized for Quasi-Resonant Converter (QRC)
- Advanced Burst-Mode Operation for under 1 W Standby Power Consumption
- Pulse-by-Pulse Current Limit
- Overload Protection (OLP) – Auto Restart
- Over-Voltage Protection (OVP) – Auto Restart
- Abnormal Over-Current Protection (AOCP) – Latch
- Internal Thermal Shutdown (TSD) – Latch
- Under-Voltage Lockout (UVLO) with Hysteresis
- Low Startup Current (Typical: 25 μ A)
- Internal High Voltage SenseFET
- Built-in Soft-Start (20 ms)
- Extended Quasi-Resonant Switching

Applications

- CTV
- Audio Amplifier

Description

A Quasi-Resonant Converter (QRC) typically shows lower EMI and higher power conversion efficiency compared to a conventional hard-switched converter with a fixed switching frequency. Therefore, a QRC is well suited for noise-sensitive applications, such as color TV and audio. Each product in the FSCQ series contains an integrated Pulse Width Modulation (PWM) controller and a SenseFET. This series is specifically designed for quasi-resonant off-line Switch Mode Power Supplies (SMPS) with minimal external components. The PWM controller includes an integrated fixed frequency oscillator, under-voltage lockout, leading-edge blanking (LEB), optimized gate driver, internal soft-start, temperature-compensated precise current sources for loop compensation, and self-protection circuitry. Compared with a discrete MOSFET and PWM controller solution, the FSCQ series can reduce total cost, component count, size, and weight; while increasing efficiency, productivity, and system reliability. These devices provide a basic platform for cost-effective designs of quasi-resonant switching flyback converters.

Pin Descriptions

Pin	Name	Description
1	DRAIN	This pin is the high-voltage power SenseFET drain connection.
2	GND	This pin is the control ground and the SenseFET source.
3	VCC	This pin is the positive supply input. This pin provides internal operating current for both startup and steady-state operation.
4	VFB	This pin is internally connected to the inverting input of the PWM comparator. The collector of an opto-coupler is typically tied to this pin. For stable operation, a capacitor should be placed between this pin and GND. If the voltage of this pin reaches 7.5 V, the overload protection triggers, which results in the FPS™ shutting down.
5	SYNC	This pin is internally connected to the sync detect comparator for quasi-resonant switching. In normal quasi-resonant operation, the threshold of the sync comparator is 4.6 V / 2.6 V. Whereas, the sync threshold is changed to 3.0 V / 1.8 V in an extended quasi-resonant operation.

Functional Description

1. Startup: Figure 25 shows the typical startup circuit and the transformer auxiliary winding for the FSCQ series. Before the FSCQ series begins switching, it consumes only startup current (typically 25 μ A). The current supplied from the AC line charges the external capacitor (C_{a1}) that is connected to the V_{CC} pin. When V_{CC} reaches the start voltage of 15 V (V_{START}), the FSCQ series begins switching and its current consumption increases to I_{OP} . Then, the FSCQ series continues normal switching operation and the power required is supplied from the transformer auxiliary winding, unless V_{CC} drops below the stop voltage of 9 V (V_{STOP}). To guarantee stable operation of the control IC, V_{CC} has under-voltage lockout (UVLO) with 6 V hysteresis. Figure 26 shows the relationship between the operating supply current of the FSCQ series and the supply voltage (V_{CC}).

Figure 25. Startup Circuit

Figure 26. Relationship between Operating Supply Current and V_{CC} Voltage

The minimum average of the current supplied from the AC is given by:

$$I_{SUP}^{AVG} = \left(\frac{\sqrt{2 \cdot V_{AC}^{MIN}}}{\pi} - \frac{V_{START}}{2} \right) \cdot \frac{1}{R_{STR}} \quad (1)$$

where V_{ac}^{min} is the minimum input voltage, V_{START} is the FSCQ series' start voltage (15 V), and R_{str} is the startup resistor. The startup resistor should be chosen so that I_{sup}^{avg} is larger than the maximum startup current (50 μ A).

Once the resistor value is determined, the maximum loss in the startup resistor is obtained as:

$$LOSS = \frac{1}{R_{STR}} \cdot \left(\frac{(V_{AC}^{MAX})^2}{2} + V_{START}^2 - \frac{2\sqrt{2} \cdot V_{START} \cdot V_{AC}^{MAX}}{\pi} \right) \quad (2)$$

where V_{ac}^{max} is the maximum input voltage.

The startup resistor should have properly rated dissipation wattage.

2. Synchronization: The FSCQ series employs a quasi-resonant switching technique to minimize the switching noise and loss. In this technique, a capacitor (C_r) is added between the MOSFET drain and the source, as shown in Figure 27. The basic waveforms of the quasi-resonant converter are shown in Figure 28. The external capacitor lowers the rising slope of the drain voltage to reduce the EMI caused when the MOSFET turns off. To minimize the MOSFET's switching loss, the MOSFET should be turned on when the drain voltage reaches its minimum value, as shown in Figure 28.

Figure 27. Synchronization Circuit

Figure 28. Quasi-Resonant Operation Waveforms

The minimum drain voltage is indirectly detected by monitoring the V_{CC} winding voltage, as shown in Figure 27 and Figure 29. Choose voltage dividers, R_{SY1} and R_{SY2} , so that the peak voltage of the sync signal (V_{syk}) is lower than the OVP voltage (12 V) to avoid triggering OVP in normal operation. It is typical to set V_{syk} to be lower than OVP voltage by 3–4 V. To detect the optimum time to turn on MOSFET, the sync capacitor (C_{SY}) should be determined so that t_R is the same with t_Q , as shown in Figure 29. The t_R and t_Q are given as:

$$t_R = R_{SY2} \cdot C_{SY} \cdot \ln \left(\frac{V_{CO}}{2.6} \cdot \frac{R_{SY2}}{R_{SY1} + R_{SY2}} \right) \quad (3)$$

$$t_Q = \pi \cdot \sqrt{L_m \cdot C_{eo}} \quad (4)$$

$$V_{CO} = \frac{N_a \cdot (V_o + V_{FO})}{N_s} - V_{Fa} \quad (5)$$

where:

L_m is the primary side inductance of the transformer;

N_s is the number of turns for the output winding;

N_a is the number of turns for the V_{CC} winding;

V_{FO} is the diode forward-voltage drop of the output winding;

V_{Fa} is the diode forward-voltage drop of the V_{CC} winding; and

C_{eo} is the sum of the output capacitance of the MOSFET and the external capacitor, C_r .

Figure 29. Normal QR Operation Waveforms

Figure 30. Extended Quasi-Resonant Operation

In general, the QRC has a limitation in a wide load range application, since the switching frequency increases as the output load decreases, resulting in a severe switching loss in the light load condition. To overcome this limitation, the FSCQ series employs an extended quasi-resonant switching operation. Figure 30 shows the mode change between normal and extended quasi-resonant operations. In the normal quasi-resonant operation, the FSCQ series enters into the extended quasi-resonant operation when the switching frequency exceeds 90 kHz as the load reduces. To reduce the switching frequency, the MOSFET is turned on when the drain voltage reaches the second minimum level, as shown in Figure 31. Once the FSCQ series enters into the extended quasi-resonant operation, the first sync signal is ignored. After the first sync signal is applied, the sync threshold levels are changed from 4.6 V and 2.6 V to 3 V and 1.8 V, respectively, and the MOSFET turn-on time is synchronized to the second sync signal. The FSCQ series returns to its normal quasi-resonant operation when the switching frequency reaches 45 kHz as the load increases.

Figure 31. Extended QR Operation Waveforms

3. Feedback Control: The FSCQ series employs current mode control, as shown in Figure 32. An opto-coupler (such as Fairchild's H11A817A) and shunt regulator (such as Fairchild's KA431) are typically used to implement the feedback network. Comparing the feedback voltage with the voltage across the R_{sense} resistor, plus an offset voltage, makes it possible to control the switching duty cycle. When the reference pin voltage of the shunt regulator exceeds the internal reference voltage of 2.5 V, the opto-coupler LED current increases, pulling down the feedback voltage and reducing the duty cycle. This typically occurs when input voltage is increased or output load is decreased.

3.1 Pulse-by-Pulse Current Limit: Because current mode control is employed, the peak current through the SenseFET is limited by the inverting input of the PWM comparator (V_{fb}^*) as shown in Figure 32. The feedback current (I_{FB}) and internal resistors are designed so that the maximum cathode voltage of diode D_2 is about 2.8 V, which occurs when all I_{FB} flows through the internal resistors. Since D_1 is blocked when the feedback voltage (V_{fb}) exceeds 2.8 V, the maximum voltage of the cathode of D_2 is clamped at this voltage, thus clamping V_{fb}^* . Therefore, the peak value of the current through the SenseFET is limited.

3.2 Leading Edge Blanking (LEB): At the instant the internal SenseFET is turned on, there is usually a high current spike through the SenseFET, caused by the external resonant capacitor across the MOSFET and secondary-side rectifier reverse recovery. Excessive voltage across the R_{sense} resistor can lead to incorrect feedback operation in the current mode PWM control. To counter this effect, the FSCQ series employs a leading edge blanking (LEB) circuit. This circuit inhibits the PWM comparator for a short time (t_{LEB}) after the Sense FET is turned on.

Figure 32. Pulse Width Modulation (PWM) Circuit

4. Protection Circuits: The FSCQ series has several self-protective functions such as overload protection (OLP), abnormal over-current protection (AOCP), over-voltage protection (OVP), and thermal shutdown (TSD). OLP and OVP are auto-restart mode protections, while TSD and AOCP are latch mode protections. Because these protection circuits are fully integrated into the IC without external components, the reliability can be improved without increasing cost.

- **Auto-Restart Mode Protection:** Once the fault condition is detected, switching is terminated and the SenseFET remains off. This causes V_{CC} to fall. When V_{CC} falls to the under voltage lockout (UVLO) stop voltage of 9 V, the protection is reset and the FSCQ series consumes only startup current (25 μ A). Then, the V_{CC} capacitor is charged up, since the current supplied through the startup resistor is larger than the current that the FPS consumes. When V_{CC} reaches the start voltage of 15 V, the FSCQ series resumes its normal operation. If the fault condition is not removed, the SenseFET remains off and V_{CC} drops to stop voltage again. In this manner, the auto-restart can alternately enable and disable the switching of the power SenseFET until the fault condition is eliminated (see Figure 33).
- **Latch Mode Protection:** Once this protection is triggered, switching is terminated and the SenseFET remains off until the AC power line is unplugged. Then, V_{CC} continues charging and discharging between 9 V and 15 V. The latch is reset only when V_{CC} is discharged to 6 V by unplugging the AC power line.

Figure 33. Auto Restart Mode Protection

4.1 Overload Protection (OLP): Overload is defined as the load current exceeding its normal level due to an unexpected abnormal event. In this situation, the protection circuit should trigger to protect the SMPS. However, even when the SMPS is in the normal operation, the over load protection circuit can be triggered during the load transition. To avoid this undesired operation, the overload protection circuit is designed to trigger after a specified time to determine whether it is a transient situation or an overload situation. Because of the pulse-by-pulse current limit capability, the maximum peak current through the SenseFET is limited, and therefore the maximum input power is restricted with a given input voltage. If the output consumes more than this maximum power, the output voltage (V_o) decreases below the set voltage. This reduces the current through the opto-coupler LED, which also reduces the opto-coupler transistor current, thus increasing the feedback voltage (V_{fb}). If V_{fb} exceeds 2.8 V, D_1 is blocked, and the 5 μ A current source starts to charge C_B slowly up to V_{CC} . In this condition, V_{fb} continues increasing until it reaches 7.5 V, then the switching operation is terminated as shown in Figure 34. The delay for shutdown is the time required to charge C_B from 2.8 V to 7.5 V with 5 μ A. In general, a 20–50 ms delay is typical for most applications. OLP is implemented in auto restart mode.

Figure 34. Overload Protection

4.2 Abnormal Over Current Protection (AOCP): When the secondary rectifier diodes or the transformer pins are shorted, a steep current with extremely high di/dt can flow through the SenseFET during the LEB time. Even though the FSCQ series has OLP (Overload Protection), it is not enough to protect the FSCQ series in that abnormal case, since severe current stress will be imposed on the SenseFET until the OLP triggers. The FSCQ series has an internal AOCP (Abnormal Over-Current Protection) circuit as shown in Figure 35. When the gate turn-on signal is applied to the power SenseFET, the AOCP block is enabled and monitors the current through the sensing resistor. The voltage across the resistor is then compared with a preset AOCP level. If the sensing resistor voltage is greater than the AOCP level, the set signal is applied to the latch, resulting in the shutdown of SMPS. This protection is implemented in the latch mode.

Figure 35. AOCP Block

4.3 Over-Voltage Protection (OVP): If the secondary side feedback circuit malfunctions or a solder defect causes an open in the feedback path, the current through the opto-coupler transistor becomes almost zero. Then, V_{fb} climbs up in a similar manner to the over load situation, forcing the preset maximum current to be supplied to the SMPS until the over load protection triggers. Because more energy than required is provided to the output, the output voltage may exceed the rated voltage before the overload protection triggers, resulting in the breakdown of the devices in the secondary side. In order to prevent this situation, an over voltage protection (OVP) circuit is employed. In general, the peak voltage of the sync signal is proportional to the output voltage and the FSCQ series uses a sync signal instead of directly monitoring the output voltage. If the sync signal exceeds 12 V, an OVP is triggered resulting in a shutdown of SMPS. In order to avoid undesired triggering of OVP during normal operation, the peak voltage of the sync signal should be designed to be below 12 V. This protection is implemented in the auto restart mode.

4.4 Thermal Shutdown (TSD): The SenseFET and the control IC are built in one package. This makes it easy for the control IC to detect abnormal over temperature of the SenseFET. When the temperature exceeds approximately 150°C, the thermal shutdown triggers. This protection is implemented in the latch mode.

5. Soft Start: The FSCQ series has an internal soft-start circuit that increases PWM comparator's inverting input voltage together with the SenseFET current slowly after it starts up. The typical soft start time is 20 ms. The pulse width to the power switching device is progressively increased to establish the correct working conditions for transformers, inductors, and capacitors. Increasing the pulse width to the power switching device also helps prevent transformer saturation and reduces the stress on the secondary diode during startup. For a fast build up of the output voltage, an offset is introduced in the soft-start reference current.

6. Burst Operation: To minimize the power consumption in the standby mode, the FSCQ series employs burst operation. Once FSCQ series enters burst mode, FSCQ series allows all output voltages and effective switching frequency to be reduced. Figure 36 shows the typical feedback circuit for C-TV applications. In normal operation, the picture on signal is applied and the transistor Q₁ is turned on, which decouples R₃, D_Z and D₁ from the feedback network. Therefore, only V_{O1} is regulated by the feedback circuit in normal operation and determined by R₁ and R₂ as:

$$V_{O1}^{NORM} = 2.5 \cdot \left(\frac{R_1 + R_2}{R_2} \right) \quad (6)$$

In standby mode, the picture ON signal is disabled and the transistor Q₁ is turned off, which couples R₃, D_Z, and D₁ to the reference pin of KA431. Then, V_{O2} is determined by the Zener diode breakdown voltage. Assuming that the forward voltage drop of D₁ is 0.7V, V_{O2} in standby mode is approximately given by:

$$V_{O2}^{STBY} = V_Z + 0.7 + 2.5 \quad (7)$$

Figure 36. Typical Feedback Circuit to Drop Output Voltage in Standby Mode

Figure 38 shows the burst mode operation waveforms. When the picture ON signal is disabled, Q₁ is turned off and R₃ and D_Z are connected to the reference pin of KA431 through D₁. Before V_{O2} drops to V_{O2}^{stby}, the voltage on the reference pin of KA431 is higher than 2.5 V, which increases the current through the opto LED. This pulls down the feedback voltage (V_{FB}) of FSCQ series and forces FSCQ series to stop switching. If the switching is disabled longer than 1.4 ms, FSCQ series enters into burst operation and the operating current is reduced from I_{OP} to 0.25 mA (I_{OB}). Since there is no switching, V_{O2} decreases until it reaches V_{O2}^{stby}. As V_{O2} reaches V_{O2}^{stby}, the current through the opto LED decreases allowing the feedback voltage to rise. When the feedback voltage reaches 0.4 V, FSCQ series resumes switching with a predetermined peak drain current of 0.9 A. After burst switching for 1.4 ms, FSCQ series stops switching and checks the feedback voltage. If the feedback voltage is below 0.4 V, FSCQ series stops switching until the feedback voltage increases to 0.4 V. If the feedback voltage is above 0.4 V, FSCQ series goes back to the normal operation. The output voltage drop circuit can be implemented alternatively, as shown in Figure 37. In the circuit, the FSCQ series goes into burst mode, when picture off signal is applied to Q₁. Then, V_{O2} is determined by the Zener diode breakdown voltage. Assuming that the forward voltage drop of opto LED is 1 V, the approximate value of V_{O2} in standby mode is given by:

$$V_{O2}^{STBY} = V_Z + 1 \quad (8)$$

DISCLAIMER

FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION, OR DESIGN. TO OBTAIN THE LATEST, MOST UP-TO-DATE DATASHEET AND PRODUCT INFORMATION, VISIT OUR WEBSITE AT [HTTP://WWW.FAIRCHILDSEMI.COM](http://www.fairchildsemi.com). FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS. THESE SPECIFICATIONS DO NOT EXPAND THE TERMS OF FAIRCHILD'S WORLDWIDE TERMS AND CONDITIONS, SPECIFICALLY THE WARRANTY THEREIN, WHICH COVERS THESE PRODUCTS.

AUTHORIZED USE

Unless otherwise specified in this data sheet, this product is a standard commercial product and is not intended for use in applications that require extraordinary levels of quality and reliability. This product may not be used in the following applications, unless specifically approved in writing by a Fairchild officer: (1) automotive or other transportation, (2) military/aerospace, (3) any safety critical application – including life critical medical equipment – where the failure of the Fairchild product reasonably would be expected to result in personal injury, death or property damage. Customer's use of this product is subject to agreement of this Authorized Use policy. In the event of an unauthorized use of Fairchild's product, Fairchild accepts no liability in the event of product failure. In other respects, this product shall be subject to Fairchild's Worldwide Terms and Conditions of Sale, unless a separate agreement has been signed by both Parties.

ANTI-COUNTERFEITING POLICY

Fairchild Semiconductor Corporation's Anti-Counterfeiting Policy. Fairchild's Anti-Counterfeiting Policy is also stated on our external website, www.fairchildsemi.com, under Terms of Use

Counterfeiting of semiconductor parts is a growing problem in the industry. All manufacturers of semiconductor products are experiencing counterfeiting of their parts. Customers who inadvertently purchase counterfeit parts experience many problems such as loss of brand reputation, substandard performance, failed applications, and increased cost of production and manufacturing delays. Fairchild is taking strong measures to protect ourselves and our customers from the proliferation of counterfeit parts. Fairchild strongly encourages customers to purchase Fairchild parts either directly from Fairchild or from Authorized Fairchild Distributors who are listed by country on our web page cited above. Products customers buy either from Fairchild directly or from Authorized Fairchild Distributors are genuine parts, have full traceability, meet Fairchild's quality standards for handling and storage and provide access to Fairchild's full range of up-to-date technical and product information. Fairchild and our Authorized Distributors will stand behind all warranties and will appropriately address any warranty issues that may arise. Fairchild will not provide any warranty coverage or other assistance for parts bought from Unauthorized Sources. Fairchild is committed to combat this global problem and encourage our customers to do their part in stopping this practice by buying direct or from authorized distributors.

PRODUCT STATUS DEFINITIONS

Definition of Terms

Datasheet Identification	Product Status	Definition
Advance Information	Formative / In Design	Datasheet contains the design specifications for product development. Specifications may change in any manner without notice.
Preliminary	First Production	Datasheet contains preliminary data; supplementary data will be published at a later date. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve design.
No Identification Needed	Full Production	Datasheet contains final specifications. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve the design.
Obsolete	Not In Production	Datasheet contains specifications on a product that is discontinued by Fairchild Semiconductor. The datasheet is for reference information only.
